ABSTRACT. Twelve polymorphic microsatellites from the (AG)₁₃ and (CA)₁₃ enriched genomic libraries of *Miichthys miiuy* were isolated and characterized in a test population; the number of alleles ranged from two to nine. The observed and expected heterozygosities ranged from 0.1923 to 1.0000 and from 0.2633 to 0.8337, respectively. Three loci deviated from Hardy-Weinberg equilibrium, and linkage disequilibrium between five pairs of loci was significant. These polymorphic microsatellite loci can be used for genetic diversity analysis and molecular-assisted breeding of *M. miiuy*.

Key words: *Miichthys miiuy*; Microsatellite; Molecular marker
INTRODUCTION

Miuy croaker, *Miichthys miuy*, is a promising marine fish species for culture in China and is distributed throughout eastern China (Zhang and Hong, 2000; Shan et al., 2008a,b). High mortality and poor growth have been frequently found during artificial larval rearing, which is hindering the mass production of this fish (Shan et al., 2009). Hence, an important approach to improve this situation is to culture strains of fish with enhanced resistance to some major diseases. Artificial breeding of miuy croaker with disease resistance and better growth has been conducted in China. However, molecular marker-assisted selective breeding is still lacking because it demands analysis of genetic characteristics and quantitative trait locus (QTL) markers of selected strains using molecular markers. Although it is an important commercial fish species, little is known about the genetic information of miuy croaker. There are no abundant molecular markers such as microsatellites isolated from this species. Lack of enough polymorphic molecular markers has limited development of molecular phylogeny, population structure, conservation genetics, and assisted selective breeding in this species. Thus, screening for polymorphic microsatellite or other molecular markers is necessary for analyzing genetic information in the miuy croaker. Microsatellites are useful molecular markers to study population structure and genetic evolutionary information (Liu et al., 2009). In the present study, 12 polymorphic microsatellite DNA markers were developed from two dinucleotide-enriched genomic libraries created using fast isolation by amplified fragment length polymorphism of sequences containing repeats (FIASCO method; Zane et al., 2002).

MATERIAL AND METHODS

Thirty individuals of miuy croaker were captured from the Zhoushan fishing ground of the East Sea. Total genomic DNA was extracted from gills using the TIANamp Genomic DNA Kit (Tiangen) following manufacturer instructions. Two enriched partial genomic libraries for the repeat motif (AG)$_{13}$ and (CA)$_{13}$ were constructed essentially using DNA from one individual and following the FIASCO protocol. In brief, genomic DNA was digested using the *Mse*I restriction enzyme (MBI) and DNA fragments between 300 and 1000 bp were isolated on 1.2% agarose gel. These fragments were ligated to adapters OligoA (5'-TACTCAGGACTCAT-3') and OligoB (5'-GACGATGAGTCCTGAG-3'), and then amplified by polymerase chain reaction (PCR) using *Mse*I-N primers (5'-GATGAGTCCTGAGTAAN-3'). Then genomic DNA fragments containing simple sequence repeat (SSR) sequences were captured by hybridization to (AG)$_{13}$ and (CA)$_{13}$ biotin-labeled probes. Captured fragments were ligated to pGEM-T vectors (Promega) and transformed into TOP10 competent cells following the standard protocol. Positive clones (N = 106) were screened via PCR with T7/SP6 primers, sequenced using T7 primer on an ABI 3730 automated sequencer. From the two libraries, 91 clones were sequenced successfully and 55 sequences contained sufficient repeat motifs. Some possessed only three to seven repeats, which held less potential for useful polymorphism. Primers for these loci were designed using the PRIMER PREMIER 5.0 software. Forty-four primer pairs were designed from 44 sequences as the remaining SSR sequences were too close to the cloning site to design primers.

Polymorphism at each locus was determined using 30 individuals. PCR amplifications were carried out in 25-μL volumes containing 2.5 μL 10X PCR buffer, 1.5 mM MgCl$_2$, 0.2 mM
dNTPs, 0.2 μM of the forward and reverse primers, and 1.5 units of Taq polymerase (Takara). Cycling conditions were 94°C for 4 min followed by 30 cycles of 94°C for 40 s, annealing temperature for 45 s (see Table 1), and 72°C for 40 s, followed by 1 cycle of 72°C for 5 min and then holding at 4°C. PCR amplification was performed on an ABI 9700 thermal cycler. Denatured amplified products were separated on 6% denaturing polyacrylamide (19:1 acrylamide:biacrylamide) gels using silver staining (Xu et al., 2009). A denatured pBR322 DNA/MspI molecular weight marker (Tiangen) was used as a size standard to identify alleles (Xu et al., 2009). POPGENE32 (Yeh and Boyle, 1997) and ARLEQUIN 3.11 softwares (Schneider et al., 2000) were used to calculate the number of alleles, observed and expected heterozygosity, violation of Hardy-Weinberg equilibrium (HWE) expectations, and genotypic linkage disequilibrium. All results for multiple tests were corrected using Bonferroni’s correction (Rice, 1989).

RESULTS AND DISCUSSION

Details for the newly developed 12 microsatellite loci and variability measures across 30 individuals are summarized in Table 1.

*Indicates significant deviation from HWE after Bonferroni correction (P < 0.0042).

In total, 12 of 44 amplicons from the microsatellite-enriched genomic libraries were successfully amplified and shown to be polymorphic in the miiuy croaker. The 12 sequences containing microsatellite loci were deposited in GenBank (GU084247-GU084258). No similarity was found between the 12 microsatellites and the published sequences in GenBank. The
number of alleles per locus ranged from 2 to 9, and observed and expected heterozygosity ranged from 0.1923 to 1.0000 and from 0.2633 to 0.8337, respectively. The remaining 32 loci were monomorphic and failed to amplify. Three loci (Mimi-3, Mimi-6 and Mimi-12) deviated from the HWE expectations in the sampled population after Bonferroni’s correction (adjusted P value = 0.0042); the remaining 9 loci conformed to HWE. Mimi-3 and Mimi-12 deviated from the HWE possibly due to the presence of null alleles or the existence of subpopulations, but it is interesting to note that the locus Mimi-6 has the highest number of repeats and the most alleles, and the observed heterozygosity of 1 is very extreme. Furthermore, null alleles were found in five loci (Mimi-3, Mimi-12, Mimi-15, Mimi-19, and Mimi-30) and stuttering errors were found in one locus (Mimi-3) using MICRO-CHECKER (Van Oosterhout et al., 2004) (Bonferroni’s correction), but no evidence of allelic dropout was found in any of the loci (Bonferroni’s correction). In total, 66 pairwise tests for linkage disequilibrium among the 12 loci were non-significant (P > 0.05, adjusted P value = 0.0008) except for five pairs of loci (Mimi-3 and Mimi-12; Mimi-3 and Mimi-19; Mimi-3 and Mimi-30; Mimi-4 and Mimi-30; Mimi-24 and Mimi-30). These polymorphic microsatellite loci in miuuy croaker will enable studies of the genetic variation, population structure, conservation genetics, and molecular assisted selective breeding of the miuuy croaker in the future.
