ABSTRACT. RPS14 is a component of the 40S ribosomal subunit encoded by the RPS14 gene and is required for its maturation. The cDNA and the genomic sequence of RPS14 were cloned successfully from the giant panda (Ailuropoda melanoleuca) using RT-PCR technology and touchdown-PCR, respectively; they were both sequenced and analyzed. The length of the cloned cDNA fragment was 492 bp; it contained an open-reading frame of 456 bp, encoding 151 amino acids. The length of the genomic sequence is 3421 bp; it contains four exons and three introns. Alignment analysis indicates that the nucleotide sequence shares a high degree of homology with those of Homo sapiens, Bos taurus, Mus musculus, Rattus norvegicus, Gallus gallus, Xenopus laevis, and Danio rerio (93.64, 83.37, 92.54, 91.89, 87.28, 84.21, and 84.87%, respectively). Comparison of the deduced amino acid sequences of the giant panda with those of these other species revealed that the RPS14 of giant panda is highly homologous with those of B. taurus, R. norvegicus and D. rerio (85.99, 99.34 and 99.34%, respectively), and is 100% identical with the others. This degree of conservation of RPS14 suggests evolutionary selection. Topology prediction shows that there
are two N-glycosylation sites, three protein kinase C phosphorylation sites, two casein kinase II phosphorylation sites, four N-myristoylation sites, two amidation sites, and one ribosomal protein S11 signature in the RPS14 protein of the giant panda. The \textit{RPS14} gene can be readily expressed in \textit{Escherichia coli}. When it was fused with the N-terminally His-tagged protein, it gave rise to accumulation of an expected 22-kDa polypeptide, in good agreement with the predicted molecular weight. The expression product obtained can be purified for studies of its function.

**Key words:** cDNA cloning; \textit{RPS14}; Giant panda; Overexpression; \textit{Ailuropoda melanoleuca}; Genomic cloning

**INTRODUCTION**

Ribosomes are vital organelles, which catalyze protein synthesis in all living organisms (Ramakrishnan and Moore, 2001). Eukaryotic ribosomes consist of four RNA molecules (rRNAs) and approximately 80 different proteins and can be dissociated into a small and large subunit (Wool et al., 1995; Yoshihama et al., 2002; Hwang et al., 2004). The small subunit protein RPS14, the yeast homolog of the bacterial S11 protein, directly binds helix 23 of 18S rRNA (Fewell and Woolford Jr., 1999; Mayolo and Woolford Jr., 2003). Recently, it was reported that RPS14 is an essential protein necessary for the maturation of the 40S ribosomal subunit (Larkin et al., 1987; Moritz et al., 1990; Paulovich et al., 1993; Ford et al., 1999; Jakovljevic et al., 2004) and the processing of 18S pre-rRNA (Ferreira-Cerca et al., 2005; Ebert et al., 2008). And in the 40S subunit, RPS14 helps to form the mRNA exit channel along with its interacting protein RPS5 (Yusupov et al., 2001). Moreover, the RPS14 protein in yeast regulates its own expression, via binding to the 5' splice-site of \textit{RPS14B} pre-mRNA, which forms a stem-loop structure with a bulged region caused by imperfect complementary base pairs (Li et al., 1995). In humans, \textit{RPS14} maps to the commonly deleted region at 5q31-q32 (Boultonwood et al., 2002) and is identified as a primary candidate gene, and its loss may be a causative factor of 5q- syndrome (Boultonwood et al., 2007), which is a hematologic malignancy characterized by a distinct phenotype and interstitial deletion of the long arm of chromosome 5 (Boultonwood et al., 1994; Giagounidis et al., 2004). Since RPS14 plays such an important role and its primary structure and function in giant panda has not been defined, it is significant to clone and analyze the \textit{RPS14} gene of the giant panda and its significance lies not only in the protection of the giant panda, but also in the therapy for several kinds of human hereditary diseases.

The giant panda (\textit{Ailuropoda melanoleuca}) is a rare species currently found only in China. It is at high risk of extinction because of human population expansion and destruction of its habitat. At present, there is very little genetic information for the panda (Liao et al., 2003; Du et al., 2007; Hou et al., 2008, 2009; Zhang et al., 2009), which is an essential tool for detailed understanding of the biology of this organism. Recently, the giant panda’s draft genome sequence, which has good coverage and completeness for genes with unique sequences, has been generated and assembled (Li et al., 2010), but some genes are still incomplete in this project. Using conventional methods, we obtained the ribosomal protein (r-protein) S14 cDNA clone and genomic sequence clone from the skeletal muscle of the giant panda. In
further analysis, our data are intact and helped us clearly understand the extent of giant panda
*RPS14*. We then analyzed the sequence characteristics of the protein encoded by the cDNA
and compared it with vertebrate reported. We also overexpressed it in *Escherichia coli* using
pET28a plasmids. Consequently, our study provides scientific data for inquiring into the
hereditary traits of the gene from giant panda and these data will enrich and supplement the
information about *RPS14*.

**MATERIAL AND METHODS**

**Material**

Skeletal muscle was collected from a dead giant panda at the Wolong Conservation
Center of the Giant Panda, Sichuan, China. The collected skeletal muscle was frozen in liquid
nitrogen and then used for RNA and DNA isolation.

**DNA and RNA isolation**

A total of 500 mg muscle tissue from giant panda was ground in liquid nitrogen to a
fine powder, and the powder was suspended completely in 15 mL lysis buffer containing 10
mM Tris-HCl, pH 8.0, 100 mM EDTA and 0.5% SDS. After treatment with proteinase K (100
mg/mL, final concentration) at 55°C for 3 h, the mixture was then cooled to room temperature
and mixed with an equal volume of saturated phenol (pH 8) before being centrifuged at 5000
g at 4°C for 20 min. The supernatant was pooled and then mixed with an equal volume of 1:1
(v:v) phenol-chloroform and then centrifuged as above and the supernatant collected, from
which the DNA was precipitated by ethanol. The DNA obtained was then dissolved in TE
buffer and kept at -20°C.

Total RNAs were isolated from about 400 mg muscle tissue using the Total Tissue/
Cell RNA Extraction Kits (Waton Inc., Shanghai, China) according to manufacturer instruc-
tions. The total RNAs extracted were dissolved in DEPC (diethyl pyrocarbonate) water, and
kept at -70°C.

**Primer design, RT-PCR, cloning of RT-PCR products, and sequencing**

The polymerase chain reaction (PCR) primers were designed by Primer Premier 5.0,
based on the mRNA sequence of *RPS14* from *Homo sapiens* (NM_001025070), *Mus musculus*
(NM_020600), *Rattus norvegicus* (NM_022672), and *Gallus gallus* (NM_001030619). The
specific primers of cDNA sequences were as follows: *RPS14* forward: 5’-GGAGTCTGGAGA
AGACGCTCA-3’; *RPS14* reverse: 5’-GAGAAGTCTTGTTCACAGACG-3’.

Total RNAs were synthesized into the first-stranded cDNAs using a reverse transcrip-
tion kit with Oligo dT as the primers according to manufacturer instructions (Promega, USA).
Twenty microliters of the first-strand cDNA synthesis reaction system was included in 1 μg
total RNAs, 5 mM MgCl₂, 1 mM dNTPs, 0.5 μg Oligo dT₁₅, 10 U/μL RNase inhibitor, and 15
U AMV reverse transcriptase, and incubated at 42°C for 60 min.

The first-strand cDNA synthesized was used as a template. The total reaction volume
for DNA amplification was 25 μL. Reaction mixtures contained 1.5 mM MgCl₂, 200 μM of
each of dATP, dGTP, dCTP and dTTP (Omega, China), 0.3 μM of each primer, 5.0 units Taq plus DNA polymerase (Sangon Co., Shanghai, China). DNA amplification was performed using an MJ Research thermocycler, Model PTC-200 (Watertown, MA, USA) with a program of 4 min at 94°C, followed by 30 cycles of 1 min at 94°C, 0.5 min at 48°C and 1.5 min at 72°C, and then ended with the final extension for 10 min at 72°C. After amplification, PCR products were separated by electrophoresis on 1.5% agarose gel with 1X TAE (Tris-acetate-EDTA) buffer, stained with ethidium bromide and visualized under UV light. The expected fragments of PCR products were harvested and purified from gel using a DNA harvesting kit (Omega), and then ligated into a pMD19-T vector at 4°C for 8 h. The recombinant molecules were transformed into E. coli competent cells (DH5α), and then spread on an LB-plate containing 50 μg/mL ampicillin, 200 mg/mL IPTG (isopropyl-beta-D-thiogalactopyranoside), and 20 mg/mL X-gal. Plasmid DNA was isolated and digested by PstI and ScaI to verify the insert size. Plasmid DNA was sequenced by Huada Zhongsheng Scientific Corporation (Beijing, China).

Cloning the genomic sequence of RPS14

The PCR primers were the same as the RPS14 forward and RPS14 reverse presented above. The genomic sequence of the RPS14 gene was amplified using Touchdown-PCR with the following conditions: 94°C for 30 s, 55°C for 45 s, 72°C for 4 min in the first cycle and the annealing temperature deceased 0.5°C per cycle; after 20 cycles conditions changed to 94°C for 30 s, 45°C for 45 s, 72°C for 4 min for another 15 cycles, and then ended with the final extension for 10 min at 72°C. The fragment amplified was also purified, ligated into the clone vector and transformed into E. coli competent cells. Finally, the recombinant fragment was sequenced by Sangon.

Construction of the expression vector and overexpression of recombinant RPS14

The PCR fragment corresponding to the RPS14 polypeptide was amplified from the RPS14 cDNA clone with the forward primer, 5’-ACTGGATCCATGGCGCTCGAAG-3’ (BamHI) and reverse primer, 5’-GACGGCGGCCGTACACGAGCGCGACCA-3’ (NotI), respectively. PCR was performed at 94°C for 3 min; 30 cycles of 30 s at 94°C, 45 s at 52°C, 1 min at 72°C, and 10 min at 72°C. The amplified PCR product was cut and ligated into corresponding site of the pET28a vector (Stratagene, USA). The resulting construct was transformed into the E. coli BL21 (DE3) strain (Novagen, USA) and used for induction by adding IPTG at an OD 600 of 0.6 and culturing further for 4 h at 37°C, using the empty vector transformed BL21(DE3) as a control. The recombinant protein samples were induced after 0, 1, 1.5, 2, 2.5, and 3 h and then separated by SDS-PAGE and stained with Coomassie blue R 250.

Data analysis

The sequence data were analyzed by the GenScan software (http://genes.mit.edu/GENSCAN.html). Homology research of the giant panda RPS14 compared with the gene sequences of other species was performed using Blast 2.1 (http://www.ncbi.nlm.nih.gov/blast/). Open-reading frame (ORF) of the DNA sequence was searched using the ORF finder software (http://www.ncbi.nlm.nih.gov/gorf/gorf.html). Protein structure of the RPS14 sequence
cloned was deduced using the PredictProtein software (http://cubic.bioc.columbia.edu/predictprotein/). Prediction of the RPS14 sequence was simulated by the SWISS-MODEL software (http://swiss-model.expasy.org/).

RESULTS

Analysis of the cDNA of RPS14 from the giant panda

About 500 bp of the cDNA fragment was amplified from the giant panda with the primers RPS14 forward and RPS14 reverse (Figure 1). The length of the cDNA cloned was 492 bp.

![Figure 1](image)

**Figure 1.** Reverse transcription polymerase chain reaction products of giant panda RPS14. Lanes 1 and 2 = Amplified RPS14; M = molecular ladder DL2000.

Blast research showed that the cDNA sequence cloned is highly homologous with the RPS14 sequences from human and other mammalian species. On the basis of the high identity, we concluded that the cDNA we isolated is the cDNA encoding the giant panda RPS14 protein. The RPS14 cDNA sequence was submitted to GeneBank (accession No. HM153519). The giant panda RPS14 sequence we cloned contains 24-bp 5’-untranslated sequence and 12-bp 3’-untranslated region. An ORF of 456 bp encoding 151 amino acids was found in the cDNA (Figure 2).
Analysis of the genomic sequence of RPS14 from the giant panda

A DNA fragment of about 3500 bp was amplified with primers RPS14 forward and RPS14 reverse (Figure 3). The length of the DNA fragment cloned is 3421 bp. Comparison between the cDNA sequence and the DNA fragment sequence of the RPS14 amplified from giant panda was performed by the Lasergene software. These results indicated that the cDNA sequence is in total accordance with four short fragments in the DNA fragment, which shows that the DNA fragment amplified is the genomic sequence of the RPS14 from giant panda. The genomic sequence of the RPS14 reported in this paper has been submitted to GenBank and assigned the accession No. HM153520.

Prediction and analysis of protein functional sites in RPS14 protein of the giant panda

Primary structure analysis revealed that the molecular weight of the putative RPS14 protein of the giant panda is 16.27 kDa with a theoretical pI = 10.07. Topology prediction shows that there are two N-glycosylation sites, three protein kinase C phosphorylation sites, two casein kinase II phosphorylation sites, four N-myristoylation sites, two amidation sites, and one ribosomal protein S11 signature in the RPS14 protein of the giant panda (A. melanoleuca) (Figure 4).

Figure 4. Comparison of the amino acid sequence of RPS14 between the giant panda and seven other vertebrate species. PD = the giant panda; HM = Homo sapiens; BT = Bos taurus; MS = Mus musculus; RT = Rattus norvegicus; GG = Gallus gallus; XL = Xenopus laevis; DR = Danio rerio. Shaded letters = N-glycosylation site; double-line squares = protein kinase C phosphorylation site; underlined dots = casein kinase II phosphorylation site; single-line squares = N-myristoylation site; solid lines = amidation site; double solid lines = ribosomal protein S11 signature; thin dotted lines = no amino acids.
Overexpression of the RPS14 gene in E. coli

The RPS14 gene was overexpressed in E. coli using pET28a plasmids carrying strong promoter and terminator sequences derived from phage T7. For this purpose, the RPS14 gene was amplified individually by PCR and cloned in a pET28a plasmid, resulting in a gene fusion coding for a protein bearing a His-tag extension at the N-terminus. Expression was tested by SDS-PAGE analysis of protein extracts from recombinant in E. coli BL21 strains (Figure 5). The results indicated that the protein RPS14 fusion with the N-terminally His-tagged form gave rise to the accumulation of an expected 22-kDa polypeptide that formed inclusion bodies. Apparently, the recombinant protein was expressed after half an hour of induction and after 2 h reached the highest level. These results suggested that the protein is active and just the protein encoded by the RPS14 from the giant panda. The expression product obtained could be used to purify the protein and further study its function.

DISCUSSION

As determined by BLAST analysis, the nucleotide sequence RPS14 cloned from the giant panda shares a high homology with those of H. sapiens, Bos taurus, M. musculus, R. norvegicus, G. gallus, Xenopus laevis, and Danio rerio (93.64, 83.37, 92.54, 91.89, 87.28, 84.21, and 84.87%, respectively). Comparison of the deduced amino acid sequences of giant panda with those of these species showed that the RPS14 shares a high homology with that of B. taurus, R. norvegicus, and D. rerio (85.99, 99.34, and 99.34%, respectively), and is entirely identical with the rest. This striking pattern of evolutionary conservation is reasonable, as ribosomal protein genes are a group of highly conserved housekeeping genes (Wool,
1979). Furthermore, we observed that the stop codon TGA is used in giant panda, *H. sapiens*, *M. musculus* and *R. norvegicus*, while *B. taurus* and *X. laevis* is terminated with TAA and two other species terminated with TAG. Physical and chemical analysis showed that the molecular weight of the putative protein among the five mammalians is very close and that of the theoretical pI is exactly identical (Table 1).

Table 1. Molecular weight and pI of RPS14 of the giant panda and seven other vertebrate species.

The genomic sequence of *RPS14* is 3421 bp in size. A comparison of the nucleotide sequences of the genomic and cDNA sequences indicated that the genomic sequence of *RPS14* possesses four exons and three introns, which is also supported by restriction mapping of the genomic and cDNA sequences. Compared with some mammals, including *H. sapiens* (NC_000005), *M. musculus* (NC_000084), *R. norvegicus* (NC_005117), and *Canis familiaris* (NC_006586), the length of the genomic sequence, the first, second and third introns, and the 5'- and 3'-untranslated sequences are different (see Table 2). From the table we can see that *D. rerio*’s introns and *B. taurus*’s third intron differ dramatically with respect to their lengths. These diverse intron patterns in the table facilitate the evaluation of characteristics in *RPS14* evolution, although the origin and significance of various intron models remain a mystery (Rogers, 1990; Roy et al., 2003). Furthermore, we compared our data with the giant panda’s draft genome sequence counterpart (accession No. GL192580), which contains only exon 1 to exon 3 and even its exon 3 is truncated, showing that our data are intact and can supplement information on *RPS14*.

The genomic sequence of giant panda cloned is marked with a star, while the lozenge represents the counterpart published in the draft genome sequence. *C. familiaris* = *Canis familiaris*. For the complete name of the other species, see legend to Table 1.

RPS14 protein from the giant panda is extremely basic (pI = 10.07), and its Arg and Lys residues are concentrated in both termini of the protein, in which the 10 amino-terminal residues contain four lysines and one arginine, while the 11 carboxyl-terminal amino acids include six arginine residues and one lysine residue. Previous experimental studies have dem-
Giant panda ribosomal protein S14 demonstrated that S14 protein’s amino terminal (amino acid residues 1-20) was unnecessary for biological activity, and the amino acids 24-49 and 107-131 were crucial for the ribosomal protein’s biological activity, as those two segments are required for the nucleolar functions that mediate S14 incorporation into pre-ribosomal particles and for the normal function of mature cytoplasmic ribosomes (Diaz and Roufa, 1992). In addition, Cys-31, His-43, Thr-45, Gly-49, Gly-111, Ser-114, Gly-123, Met-124, Ile-126, Gly-127, Asp-131, and Thr-133 in these two domains are the structural determinants that mediate S14 incorporation into pre-ribosomal particles (Martin and Roufa, 1997). Recently, it was found that the Asn-38 is also important for ribosome assembly, while Lys-63, Arg-98 and the 10 carboxy-terminal amino acid residues, RKGGRRGRRL, are responsible for RPS14 binding to helix 23 of 18S rRNA (Mayolo and Woolford Jr., 2003). Subsequently, we enquired further into the functional sites of the amino acid sequences encoded by RPS14 genes and found that there are two N-glycosylation sites, three protein kinase C phosphorylation sites, two casein kinase II phosphorylation sites, four N-myristoylation sites, two amidation sites, and one ribosomal protein S11 signature in the RPS14 protein of the giant panda, *H. sapiens*, *M. musculus*, *R. norvegicus*, *G. gallus*, *X. laevis*, and *D. rerio*. As RPS14’s C-terminus in cattle varies widely, its functional sites are quite distinct from those species, and the discrepancy is that there is only one protein kinase C phosphorylation site, five N-myristoylation sites, and neither amidation site nor ribosomal protein S11 signature exist (Figure 4). Meanwhile, the variation near the carboxyl terminus also led to the difference of tertiary structure among all the compared species. In this paper, we described only the tertiary structure of giant panda and cattle (Figure 6) for the structures that are exactly the same among those species, with cattle excepted.

**Figure 6.** Stereo ribbon representation of panda (a) and cattle (b) were formed by partial sequences of RPS14. Compared with its homology model, the conserved sequences of giant panda are amino acid residues from 23 to 147 (E value: 5.77e-62), while the residues of cattle are confined to the area from 23 to 129 (E value: 1.21e-52).
In addition, the \textit{RPS14} cDNA was expressed efficiently in a prokaryotic organism using pET28a plasmids, and the resulting fusion protein was in accordance with the expected 22-kDa polypeptide. These results suggest that the protein is active and is just the protein encoded by the \textit{RPS14} from the giant panda (Figure 5). The expression product obtained could be used for purification and study of its function.

During the course of the research described above, the complete primary sequence for giant panda \textit{RPS14} has been determined and published. The primary purpose for the accumulation of these data is to use them to arrive at a solution for the structure of this ribosomal subunit. However, the information may also help in understanding the evolution of ribosomes, in unraveling the function of proteins, in defining the rules that govern the interaction of proteins and rRNAs. And this gene structure also provides important first steps toward understanding and carrying out further research on the genetic basis of panda’s biology, and contributes to disease control and conservation efforts for this endangered species.
